King County Housing with Multiple Linear Regression

Authors: Diane Tunnicliffe, Dana Rausch, Matthew Lipman

Notebook 2: Data Preparation

This notebook contains a breakdown of the step-by-step processes that we used to compile, scrub, and transform our data. It includes variations of narrowing our scope and explorations into the impacts that our different transformations have on the data. For the actual full process of how the data was obtained, and a full description of each data set, please see our first notebook, 'business problem and data understanding'.

```

In [182]: #create function to find distances between all points in DF and return matrix
          def find_distance(dataframe):
               Calculates distance between points of interest and houses.
               Generates a distance matrix for distances between houses and points of interes
           t.
               Calculates distance from each point in dataframe (df) to point of interest.
               Converts latitude and longitude to radians in order to calculate distance.
               Returns values as kilometers.
               Parameters:
               dataframe (Pandas DataFrame object): user input name of Pandas DataFrame.
               Returns:
               Matrix of distances.
               dist = sklearn.neighbors.DistanceMetric.get_metric('haversine')

In [193]: #geographic distance calculator
           #function that identifies the distance between a point of interest and house
           def distance to(point of interest):
                Calculates distance between point of interest and a house.
                Takes in coordinates for point of interest as latitude and longitude.
                Calculates distance from each point in dataframe (df) to point of interest.
                Uses haversine formula to calculate distance and return as kilometers.
                Can set distances as new column of dataframe by using df['new column']=distanc
           e_to(point_of_interest).
                Parameters:
                point_of_interest (float): user input coordinates (latitude,longitude).
                Returns:
                Distances in kilometers, using haversine formula.
                distance = df[['lat','long']].apply(lambda x: hs.haversine(x.tolist(), point_o

5 rows × 21 columns

R^2: 0.6308144610145117

By quantile tranforming our data to achieve a more normal distribution, we are able to achieve a higher R2 score.

```
In [258]: # saving copy of dataframe as csv file
#df.to_csv('./data/all_features_quant_transformed.csv')
```

Price Per Square Foot

While we were happy with the increasing R2 score, we wanted to experiment with a new possibility: making a predictive model for price per square foot, as opposed to just price. By honing on in on this target, our goal was to more accurately predict the value of a home based on our features.

```
In [328]: # reading the csv file
    df = pd.read_csv('data/kc_house_data.csv')
    # previewing the DataFrame
    df.head()

Narrowing down our data

We opted to use price per square foot as the factor by which to narrow our data. We removed outliers and focused on our main data by filtering for data within 1.5 standard deviations from the mean for price per square foot.

```
In [335]: # finding the data that lies within 1.5 standard deviations from the mean
          std = df.price per sqft.std()
          print('std: ',std)
          mean = df.price_per_sqft.mean()
          print('mean: ', mean)
          std_1 = mean + std
          std_1m = mean - std
          std 15 = mean + (1.5*std)
          std 15m = mean - (1.5*std)
          print('mean +1 std: ',std_1)
print('mean -1 std: ',std_1m)
          print('mean +1.5 std: ',std_15)
          print('mean -1.5 std: ',std_15m)
          std: 110.00006067814525
          mean: 264.1433683790251
          mean +1 std: 374.14342905717035
          mean -1 std: 154.14330770087986
```

mean +1.5 std: 429.143459396243 mean -1.5 std: 99.14327736180724

```
In [336]: std = df.price_per_sqft.std()
    mean = df.price_per_sqft.mean()
    std_1 = mean + std
    std_1m = mean - std
    std_15 = mean + (1.5*std)
    std_15m = mean - (1.5*std)
    # removing outliers
# focusing on data within 1.5 standard deviations from the mean
    df = df.loc[(df['price_per_sqft']<std_15) & (df['price_per_sqft']>std_15m)]

Out[373]:

	price	sqft_living	grade	lat	long	price_per_sqft	min_dist_park	closest_d
price	1.00	0.76	0.71	0.37	0.07	0.52	-0.01	
sqft_living	0.76	1.00	0.76	0.08	0.22	-0.10	-0.00	
grade	0.71	0.76	1.00	0.11	0.22	0.12	-0.01	
lat	0.37	0.08	0.11	1.00	-0.10	0.54	-0.01	
long	0.07	0.22	0.22	-0.10	1.00	-0.18	-0.01	
price_per_sqft	0.52	-0.10	0.12	0.54	-0.18	1.00	-0.00	
min_dist_park	-0.01	-0.00	-0.01	-0.01	-0.01	-0.00	1.00	
closest_distance_to_top_school	-0.35	-0.09	-0.10	-0.66	0.01	-0.50	0.01	
closest_distance_to_great_coffee	-0.19	-0.15	-0.16	-0.16	-0.31	-0.09	-0.01	
closest_distance_to_scientology	-0.30	0.04	0.03	-0.72	0.63	-0.55	-0.00	

Since closest distance to top school and closest distance to scientology have multicolinearity, creating 'interaction' column to account for this relationship.

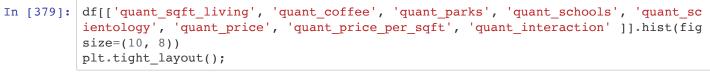

Out[374]:

	price	sqft_living	grade	lat	long	price_per_sqft	min_dist_park	closest_distance_to_top_school	
0	221900.00	1180	7	47.51	-122.26	188.05	2.04	0.26	_
1	538000.00	2570	7	47.72	-122.32	209.34	5.67	0.68	
2	180000.00	770	6	47.74	-122.23	233.77	1.34	2.00	
3	604000.00	1960	7	47.52	-122.39	308.16	2.45	1.73	
4	510000.00	1680	8	47.62	-122.05	303.57	3.72	1.18	

Our features and target do not illustrate normal distrubtions.

```
In [378]: # quantile-transforming our features and target
    from sklearn.preprocessing import QuantileTransformer
    qt = QuantileTransformer(output_distribution='normal')
    df['quant_sqft_living'] = qt.fit_transform(df[['sqft_living']])
    df['quant_coffee'] = qt.fit_transform(df[['closest_distance_to_great_coffee']])
    df['quant_parks'] = qt.fit_transform(df[['min_dist_park']])
    df['quant_schools'] = qt.fit_transform(df[['closest_distance_to_school']])
    df['quant_scientology'] = qt.fit_transform(df[['closest_distance_to_scientology'
    ]])
    df['quant_price'] = qt.fit_transform(df[['price']])
    df['quant_price_per_sqft'] = qt.fit_transform(df[['price_per_sqft']])
    df['quant_interaction'] = qt.fit_transform(df[['interaction']])
```

Our quantile transformation led to a much more normal distribution for our features and target.

```
In [380]: grade_dums = pd.get_dummies(df.grade, prefix='grade', drop_first=True)
In [381]: df = df.drop(['grade'], axis=1)
    df = pd.concat([df, grade_dums], axis=1)
    df.head()
```
